

Technical Report to the PPWB
Committee on Hydrology

NATURAL FLOW
BATTLE RIVER
AT ALBERTA-SASKATCHEWAN BOUNDARY

Prepared by:

HYDROLOGY BRANCH
TECHNICAL SERVICES DIVISION
ALBERTA DEPARTMENT OF ENVIRONMENT

SYNOPSIS

The average annual natural flow of the Battle River at the Alberta-Saskatchewan boundary is 228,000 acre-feet.

Average annual water use in the Alberta portion of the basin now amounts to 13,900 acre-feet, 6.1% of the average annual natural flow.

The present level of consumptive use (1979 level) in the Alberta portion of the Battle River basin would not have exceeded Alberta's 50% share in any of the 68 years (1912-79) analyzed. On the average, 101,000 acre-feet of Alberta's share of the Battle River flow would have been passed annually to Saskatchewan. The minimum surplus passed during any one year would have been 3,900 acre-feet in 1941.

Hydrometric records for Battle River near Ponoka, Pipestone Creek near Wetaskiwin, Coal Lake reservoir, Alberta Power reservoir and Battle River near Unwin will serve as an adequate hydrometric data base in the computation of natural flows for apportionment purposes.

The hydrometric stations for Coal Lake reservoir and for Pipestone Creek near Wetaskiwin should be operated on a continuous basis if consumptive uses are to be calculated on a continuing basis.

INTRODUCTION

Following the completion of the Prairie Provinces Water Board's Study on Determination of Natural Flow of the North Saskatchewan, South Saskatchewan, Saskatchewan, Churchill and Qu'Appelle River Basins in 1977, the Board agreed to have other interprovincial basins studied to determine if apportionment of natural flow might be required at this time. Eighteen interprovincial basins were identified and priorities assigned to the basins. The Board agreed that the eighteen basins would be studied in order of priority as funds and time became available. The Battle River natural flow study is one of this series of natural flow studies being conducted for the Prairie Provinces Water Board.

This report on the natural flow of the Battle River at the Alberta-Saskatchewan boundary describes the basin geography (chapter 2), the analytical approach of the study (chapter 3), water use within the basin (chapter 4), and the

derivation of historical natural flows (chapter 5). In chapter 6 the present (1979) level of use is analysed in conjunction with natural flows to indicate the potential for apportionment deficits.

BASIN GEOGRAPHY

The Battle River basin is situated in east-central Alberta and west-central Saskatchewan (Figure 1). Originating at Battle Lake and Pigeon Lake in central Alberta and flowing in an easterly direction, the river drains an area of 9,600 square miles and travels a channel distance of about 500 miles before crossing into Saskatchewan. In Saskatchewan, the Battle River continues its easterly route and drains an additional 1,980 square miles as it travels the remaining 150 miles to its confluence with the North Saskatchewan River.

The headwaters of the Battle River basin are situated within the eastern limits of the Western Alberta Plains, approximately 100 miles from the mountains to the west.

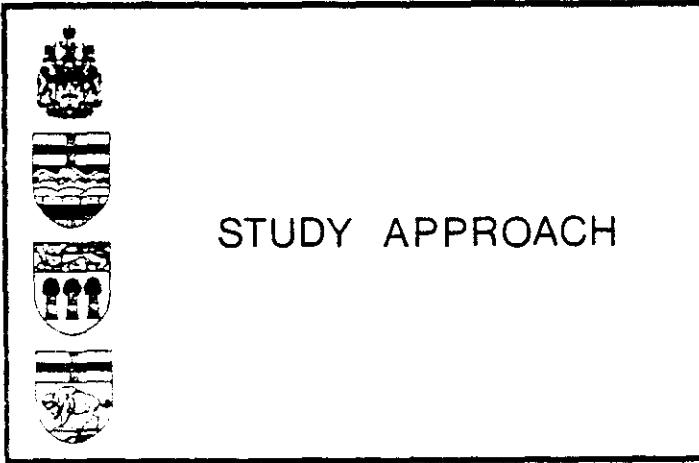

From its origin at Battle Lake, the river flows in a south-east direction meandering for a distance of 62 miles within a low well-defined valley. At Ponoka the river flows east for 30 miles and into a low, flat area near Samson

Lake. Passing through Samson Lake the river continues north for approximately 40 miles in a valley which gradually grows deeper as it approaches its confluence with Pipestone Creek.

Downstream of Pipestone Creek the river occupies a much larger, more rugged valley which was carved out by the outflow from glacial Lake Edmonton during the last glaciation some 10,000 years ago.

From its oversized valley the main Battle River flows in a generally easterly direction through the Eastern Alberta Plains and into Saskatchewan. In its downstream reaches it flows through an area characterized by gently undulating terrain with surficial deposits of till and moraine formations.

Water supply within the Battle River is partially controlled by three reservoirs located within the basin (Figure 1). Of the three reservoirs, only Coal Lake has been operated for low flow augmentation (August to November 1977) and has been fitted with a riparian outlet for such purposes. Driedmeat Lake, although originally intended to contain a riparian outlet, now depends upon manipulation of a 2-meter wide fish ladder to provide downstream flow. The Alberta Power Reservoir is used to provide cooling water for a thermal electric generating station and passes water out of the reservoir by means of a syphon fitted with various size orifice plates. All three structures have substantial spillways for the passage of larger floods.

STUDY APPROACH

The primary objective of the study is to analyze the natural monthly flow values for a historical time period (1912 to 1979) and based on the present (1979) level of water use, determine the potential for apportionment deficits now and in the foreseeable future at the Alberta-Saskatchewan boundary. The analysis may be considered as consisting of the following three components:

- i) Determining the present level of water use for the Battle River upstream of the Alberta-Saskatchewan boundary.
- ii) Determining the natural monthly flows, for the 1912 to 1979 period, for the Battle River at the Alberta-Saskatchewan boundary.
- iii) Subtracting item i from ii to determine if an apportionment deficit would have occurred in the past based on the present level of water use.

Since monthly flow records are not available at the Alberta-Saskatchewan boundary, records from the hydrometric stations - Battle River near Ponoka (05FA001), Battle River near Unwin (05FE001) and Battle River at Battleford (05FF001)

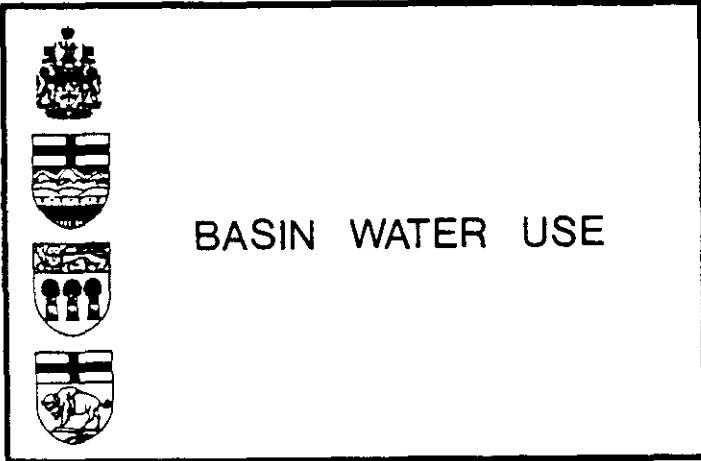

were used in the development of streamflow estimates for the Battle River at the interprovincial boundary. Also, since the monthly flow records at these sites reflect human activity in the basin and are incomplete, the natural flows at these sites as well as for Pipestone Creek near Wetaskiwin had to be reconstructed before they could be utilized in the development of natural flows at the boundary and in the apportionment analysis. The natural flows at these sites were computed using the project depletion method (see chapter 5) which required the creation of the following files at each of the previously identified gauging locations.

- i) A-File - consisting of the recorded monthly flows at each of the sites.
- ii) J-File - consisting of an array of adjustment items which must be added to or subtracted from the recorded flows in order to remove the effects of human activity (historical water use) in the basin.
- iii) B-File - consisting of the natural flows at the gauging sites. Naturalization was achieved by applying the J-Files to the pertaining A-Files.
- iv) C-File - consisting of the B-Files extended to the full 1912 to 1979 period, using simple or multiple regression on natural flow records (B-files) from other stations.

Having computed the natural flows for the 1912 to 1979 period at the above noted gauging sites, interpolation

procedures were utilized to estimate natural flows at the Alberta-Saskatchewan boundary.

The need for apportionment was analyzed by applying the estimated effects of the projects now in operation within the Alberta portion of the Battle River basin to the estimates of natural flows at the interprovincial boundary.

BASIN WATER USE

Historical basin water use (J-File) is defined as the monthly flow adjustments which must be added to the recorded flows at a gauging station in order to reconstruct the natural monthly flows at that site.

The Battle River has, and continues to supply, a diversity of water users who withdraw, discharge and consume water from various points within its basin. In order to create a table of historical basin water uses it was, therefore, necessary to identify the following items:

- i) Which projects constitute a water use?
- ii) What is the quantity of water being used by each project?
- iii) What was the period of operation for each project?
- iv) What is the time distribution of water diversions?
- v) How are time of travel adjustments to be taken into account?

4.1 Identification of Water Using Projects

As stated previously the Battle River supplies a diversity of water users. Many of the users, however,

withdraw water from or discharge water to areas which, during a year of average flow, do not contribute to the flow in the Battle River. In this regard, a basin water use has been defined as consisting solely of licenced and/or authorized projects which are located within the effective drainage area of the basin, and which consume or modify the flow which would have been experienced in the Battle River at the interprovincial boundary. While it is realized that drainage projects, land use changes, unlicenced withdrawals and withdrawals from non-effective drainage areas may have some modifying effects on flows in the Battle River, it was assumed that these effects will be negligible and therefore were not included in the analysis.

Based on the above definition, basin water uses for the Alberta portion of the Battle River were identified from Alberta Environment's computer files of water rights projects and are presented in Appendix A, Table A-1. A chronological listing of water uses for the Saskatchewan portion of the Battle River was obtained from Water Rights Branch of Saskatchewan Environment and is presented in Table A-2.

4.2 Identification of Quantity and Time of Diversions

The annual quantity and the monthly distributions of the water used within the Alberta portion of the Battle River basin were computed by the Hydrology Branch and the Planning Services Branch of Alberta Environment using the following procedure.

Licencing files provided by the Water Rights Branch of Alberta Environment were reviewed to determine which licences were located within the effective drainage area of the Battle River basin. Water licences within the effective drainage area were then categorized according to their specified purposes into one of the following groups:

- a) Stockwatering
- b) Agricultural: Irrigation
- c) Agricultural: Ducks Unlimited Projects
- d) Fish Ponds
- e) Urban Water Supply
- f) Injection
- g) Wildfowl Propogation
- h) Community Water Supply
- i) Cooling: APL Reservoir
- j) Washing Operations
- k) Flow Control: Coal Lake
- l) Miscellaneous
- m) Flood Control

Since there is a lack of information on project operation and on the variability in the monthly and annual consumption of individual licenced uses, and since the licenced amount does not necessarily represent the actual amount that it consumed each year, the following assumptions were made in order to assess the quantity and time of diversion for each of the above groups.

a) Stockwatering

Consumptive use was assumed to be 100% of the allocated amount. This amount was assumed to be diverted and effectively lost from the system during the month of April.

b) Agricultural: Irrigation

Irrigation areas were assumed to have an annual crop water requirement of two acre-feet/acre of irrigation (24 inches). The monthly crop requirements were assumed to be as follows:

May	2.64 inches	11%
June	6.24 inches	26%
July	7.68 inches	32%
Aug.	5.04 inches	21%
Sept.	2.40 inches	10%

Diversion and consumptive use for irrigation was then assumed to occur during months for which the crop requirements exceeded the monthly precipitation. The quantity diverted was assumed equal to the irrigated area multiplied by the difference between the monthly crop requirements and monthly precipitation. Monthly precipitation for areas upstream of Forestburg was assumed equal to monthly precipitation for Wetaskiwin (Table B-2) while monthly precipitation for Stettler (Table B-3) was assumed representative of areas downstream of Forestburg.

c) Agricultural: Ducks Unlimited Projects

Licenced uses within this category consisted of 17 Ducks Unlimited backflood irrigation projects most of which are located in the Ribstone Creek basin. While details as to the operation of individual projects are not available, their general opera-

tion consists of storing water during the spring runoff period (March, April) and releasing all storage in June. The number of structures operated during any one year is not constant but rather, is directly related to the spring runoff during that year.

Based on information received from Ducks Unlimited it was assumed that 50% of the total Water Rights Allocation for this category was withdrawn in March, 50% was withdrawn in April, and 100% was returned in June.

The above assumption does not consider evaporative and infiltration losses. These losses, however, are estimated at 530 ac.ft. (3.8% of total consumption in the Battle River Basin) during years when all reservoirs are being operated and substantially less during years of average or below average spring runoff.

d) Fish Ponds

Based on information in Water Rights files and on information provided by Fish and Wildlife, it was assumed that the allocated amount was diverted and held as dead storage in the first year of operation. In subsequent years, only annual evaporation losses (assumed at 12 inches) were replenished.

e) Urban Water Supply

Monthly consumptive uses for this category were determined on the basis of water use returns submitted annually by the municipalities to Water Rights Branch as well as on Municipal Water Use Questionnaires carried out by Planning Division of Alberta Environment in 1976 and updated in 1979.

f) Injection

Consumptive uses in this category were computed on the basis of monthly water use returns submitted by the licensee to the Energy Resources Conservation Board and filed in the Oil and Gas Water Use Drainage Area Codes (OGWU DAC). Since the OGWA DAC extend only as far back as 1973, consumptive uses of individual licences for years prior to 1973 were assumed equal to the average consumption of the known years (1973 to 1980).

g) Wildfowl Propogation

Consumptive uses for this category were assumed equal to 100% of the allocated amount. This amount was assumed to be diverted and effectively lost from the system during the spring runoff period - April.

h) Community Water Supply

This category refers to water diverted to service the Canadian Forces Base at Camp Wainwright.

Based on information provided by the Base

(Sgt. Holesworth) it was determined that diversion had been occurring since 1955. From 1955 to 1975 water was diverted from the Battle River to Betty Lake, effluent was released to Bushyhead Lake which had no outlet. The amount diverted during the time period was, therefore, totally consumed. In 1975 an outlet system was constructed from Bushyhead Lake to the Battle River. Consumptive uses for 1975 to 1979 were assumed equal to the amount diverted less releases from Bushyhead Lake. Diversions from the Battle River and releases from Bushyhead Lake were provided by the Base (Sgt. Holesworth).

i) Cooling: Alberta Power Reservoir

Consumptive uses from the Alberta Power Reservoir were assumed equal to the change in storage of the reservoir plus the net natural and induced evaporation from the pond. Reservoir elevations used to compute the change in storage were provided by Alberta Power Limited. Monthly precipitation and Morton estimates of evaporation used to compute the net natural evaporation are presented in Appendix B Tables B-1 to B-3. Monthly values of induced evaporation were provided by Alberta Power Limited for the 1972 to 1979 period. On the basis of the 1972 to 1979 data a relation was established for annual induced evaporation as a

function of annual energy production. The computed annual induced evaporation for years prior to 1972 was then assumed to be distributed on a monthly basis in the same fashion as the average for the 1972 to 1979 period.

j) Washing Operations

Based on information in the Water Rights files, the consumptive use for this category was estimated to be approximately 30% of the allocated amount. The 30% consumptive use was assumed equally distributed over the May to October period unless, the files listed a different period of operation.

k) Flow Control: Coal Lake Reservoir

Consumptive uses for Coal Lake Reservoir were assumed equal to the recorded flows for Pipestone Creek near Wetaskiwin (05FA012) adjusted by the ratio of effective drainage area of Pipestone Creek at its confluence with Coal Lake and at the gauging site minus releases from Coal Lake.

l) Miscellaneous

This category refers to a licence (#12128) issued for the purpose of leaching underground caverns. Consumptive use for this category was assumed at 100% of allocated amount since it is essentially an injection type of operation.

m) Flood Control

Consumptive uses for this category were assumed as negligible since losses are essentially the same as for normal river flow.

Consumptive uses for the Saskatchewan portion of the Battle River basin were supplied by Water Rights Branch of Saskatchewan Environment and are listed in Appendix A Table A-2. The time distribution of all water uses in Saskatchewan was assumed to be; 50% in April, 35% in May, 10% in June, and 5% between July and October.

4.3 Period of Operation

Based on discussions with Planning Services Branch of Alberta Environment, the period of operation for projects in all categories was assumed to commence on the year of interim licencing. The period of operation from all categories was assumed to end on the date of cancellation. The period of operation for the individual projects within the Alberta portion of the Battle River are provided in Table A-1.

4.4 Time of Travel Adjustments

Due to the relative lack of hydrometric data for the Battle River and its tributaries, travel times could only be computed for specific points along the main stem of the Battle River. The Battle River was therefore assumed to consist of five nodes. All water uses between any two nodes

were assumed to take place at the downstream node. The five nodes and the travel times between these nodes are as follows:

Node Number	Location	Travel Time (days)
1	Battle River near Ponoka	6
2	Battle River near Gwynne	6
3	Battle River near Forestburg	7
4	Battle River near Unwin	4
5	Battle River at Battleford	

The above times are assumed constant for all levels of flow.

Based on items 4.1 to 4.4, historical water uses (J-File) for the Battle River near Forestburg, Unwin and Battleford were computed using the following equation:

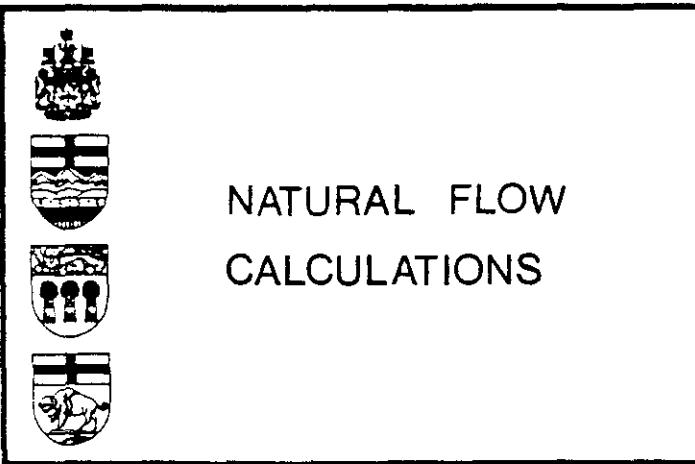

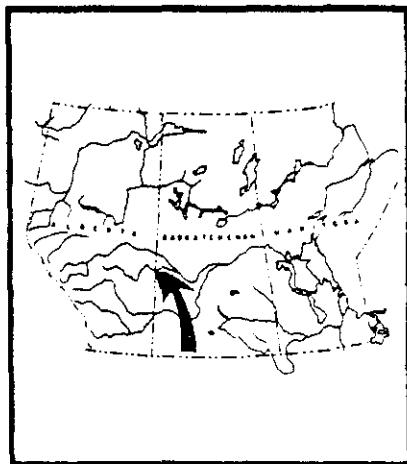

$$J(i,t) = Q(i,t) + qQ(i-1,t-1) + (1-q)Q(i-1,t) + \\ q_1Q(i-2,t-1) + (1-q_1)Q(i-2,t) + \dots$$

Where $J(i,t)$ = The adjustment which must be added to the recorded flow at node 'i' for month 't' to reconstruct the natural flow at node 'i'.

$Q(i,t)$ = The adjustment due to water uses between nodes 'i' and 'i-1' for time 't'.

q = A travel time adjustment as a fraction of a month. Travel time from the upstream node to node 'i' divided by the number of days in month 't'.

The resulting listing of adjustment items (J-Files) for the Battle River near Ponoka, Forestburg, Unwin, and Battleford are presented in Appendix D, Tables D-1 to D-4 respectively and are designated by a "J" preceding the station number.

NATURAL FLOW CALCULATIONS

5.1 Introduction

Natural flow is that quantity of water which would have been recorded under natural conditions, that is, prior to the effects of human interference. The project depletion method was used in this study to derive an estimate of natural flows.

In the process monthly natural flow arrays covering the extended 1912 to 1979 period were developed for the hydrometric gauging stations Battle River near Ponoka (05FA001) and Battle River near Unwin (05FE001).

5.2 Data Available

Hydrometric records were available for the gauging stations Battle River near Ponoka (05FA001) for the period 1913 to 1932 and 1966 to 1979, Battle River near Forestburg (05FC001) for the period 1966 to 1979, Battle River near Unwin (05FC001) for the period 1944 to 1979 and Battle River at Battleford (05FF001) for the period 1912 to 1932, 1935,

1936, and 1967 to 1979. The arrays of monthly recorded flows (A-Files) for these sites are presented in Appendix C, Tables C-1 to C-4.

5.3 Natural Flows

Historic uses (J-Files generated in section 4.0) in the Battle River basin upstream of each of the gauging stations were added to the respective recorded monthly flows (A-Files) to create an array of monthly natural flows (B-Files) for each of the four sites. The resulting arrays of monthly natural flows are presented in Appendix E, Tables E-1 to E-4.

5.4 Regression Techniques

Monthly natural flows for periods of missing records for the Battle River near Ponoka and for the Battle River near Unwin were to be estimated by regression analysis using natural flow arrays from gauging stations within the Battle River Basin. However, no combination of stations in the Battle River basin could be found which covered the entire study period. In this regard, it was necessary to introduce the following stations, which are outside the Battle River basin, into the analysis:

- i) Sturgeon River near Fort Saskatchewan (05EA001)
- ii) Red Deer River at Red Deer (05CC002)
- iii) North Saskatchewan River at Edmonton (05DF001)
- iv) North Saskatchewan River at Prince Albert (05GG001)
- v) Blindman River near Blackfalds (05CC001)

The North Saskatchewan River has been regulated since October 1961. Removal of the effect of regulation for the North Saskatchewan River at Edmonton and Prince Albert was carried out by adding the change in storage for the Bighorn and Brazeau Reservoirs (Appendix D, Tables D-5 and D-6) directly to the recorded flows at Edmonton; the changes in storage were lagged by a factor of 0.23 to account for travel times prior to being added to the recorded flows at Prince Albert. Natural flow arrays (B-Files) for the North Saskatchewan River as well as for other stations used in the analysis are presented in Appendix E.

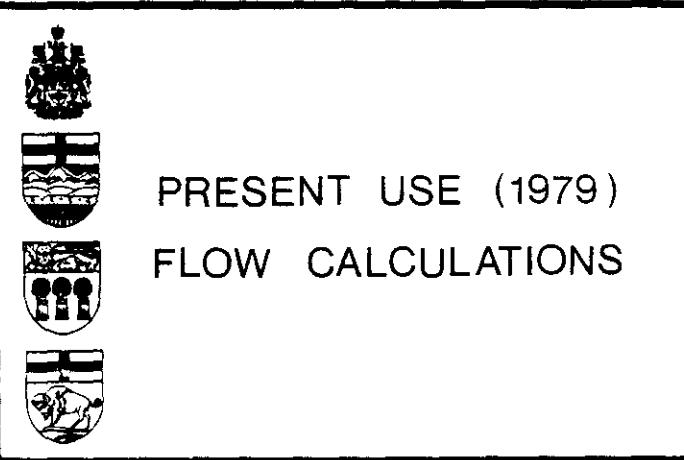

Licenced uses within the Blindman River basin are negligible. Recorded flows for the Blindman River near Blackfalds (05CC001) were, therefore, assumed to be equal to the natural flows and are presented in Appendix E, Table E-9.

B-Files for the Battle River near Ponoka and near Unwin were then correlated to the B-Files of all combinations of the other stations using a stepwise logarithmic linear regression. Missing hydrometric records were then estimated by assigning priorities to the resulting regression equations. The highest priority was given to the regression equation which gave the best estimate based on the adjusted (to account for the degrees of freedom) standard error of estimate and the adjusted coefficient of correlation. The regression equation which gave the best estimate of monthly streamflow, based on these two parameters, was assigned

priority No. 1 and was used to estimate as many missing values as possible. The regression equation assigned priority No. 2 was then used to estimate values which had not been filled in by the first priority and so on. The regression results are presented in Appendix F in a supplementary table opposite the corresponding natural flow arrays for the 1912 to 1979 period.

5.5 Natural Flows at Project Sites

Natural flows for the Battle River at the Alberta-Saskatchewan Boundary were based entirely on natural flow data derived for the Battle River at Unwin. The transfer of the natural flow array from Unwin to the interprovincial boundary was carried out by multiplying the monthly natural flows at Unwin by the ratio of the effective drainage area at the interprovincial boundary to the effective drainage area at Unwin. Similarly, the natural flows for the Coal Lake local area were estimated by multiplying the natural flows for the Battle River at Ponoka (C05FA001) by the ratio of the respective effective drainage areas. Natural flows for Pipestone Creek were computed by multiplying the extended flows for the Battle River near Ponoka (C05FA001) by .5964, the ratio of the recorded flows at the two sites. The natural flows at these latter sites were used in the apportionment section of the study. The results are presented in Appendix G, Tables G-1 to G-3.

This section describes the effect of the present level of water use on the historical natural flows. This was done by assuming that the present uses have existed since 1912 and by super-imposing those uses on the calculated natural flows for the period 1912 to 1979.

6.1 Calculation of Uses

Monthly arrays of uses were created for the following:

- 1) for all minor users upstream of the interprovincial border assuming the user demand to be constant and at its present (1979) level, 2) for evaporation from Coal Lake Reservoir assuming the lake had a constant surface area of 2,740 acres (surface area at FSL) and 3) for evaporation from the Alberta Power Reservoir assuming a constant surface area of 700 acres (average surface area).

An array of monthly demands from minor users at their present level of consumption (as described in Section 4.0) is presented in Appendix H Table H-3.

Coal Lake initially had a contributing drainage area of approximately 67.3 square miles and an average surface area of approximately 2,200 acres. In August of 1973 a dam was constructed to create the Coal Lake Reservoir. The construction of the dam increased the surface area of the lake to a full supply level (FSL) surface area of approximately 2,740 acres. Since the median annual runoff from this region is significantly lower than the mean annual runoff, the runoff from the initial drainage area of Coal Lake cannot, during most years, offset the evaporation from the initial lake surface area. Consequently, during most years the inflow from Pipestone Creek has to offset evaporation losses from an area much larger than that of the incremental lake surface area created by the dam. In addition spills from the reservoir do not take place unless the reservoir is above FSL. In view of the above, it has been assumed that evaporation losses and licenced consumptive uses from Coal Lake are replenished first by the runoff from the Coal Lake local drainage area and then by the inflow from Pipestone Creek. Any remaining deficits are carried over and added on to the next month's deficit or until such time as the reservoir reaches FSL. In addition, since Coal Lake and its contributary drainage area have historically been considered as not contributing to the flow in the Battle River, evaporation losses and licenced consumptive uses replenished by the runoff from the local

drainage area for Coal Lake were not considered as historical uses. Deficits which were replenished by the inflow from Pipestone Creek were treated as historical uses since runoff from this area would have contributed to the flows in the Battle River. An array of the monthly evaporation and consumptive uses from Coal Lake if it had been at its present level of development for the entire study period is presented in Appendix H, Table H-1. An array of evaporation and consumptive uses which were made up by flow from Pipestone Creek and which are considered basin consumptive uses is presented in Table H-4.

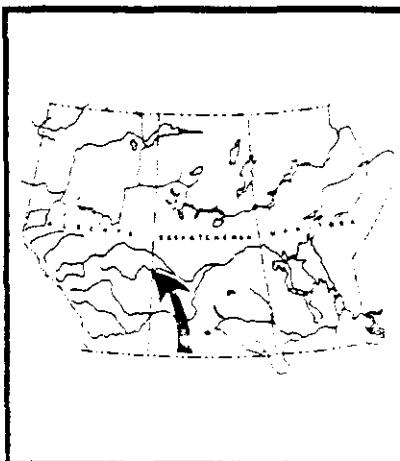

Induced evaporation from the Alberta Power Reservoir was considered equal to the average for the 1977 to 1979 period and is included within the array of minor uses. Natural evaporation was assumed to be equal to the evaporation for Lacombe (Table B-1) less the precipitation for Stettler (Table B-3) assuming a constant lake surface area of 700 acres. An array of the water uses due to natural evaporation which would have been experienced if the reservoir had been in operation for the entire study period is presented in Appendix H, Table H-2.

The total present (1979) level of water use which would have been experienced at the Alberta-Saskatchewan boundary is presented in Appendix H, Table H-5.

6.2 Comparison to Apportionment Principle

An analysis was made to determine if Alberta would have exceeded its 50% share of the natural flow of the Battle River at the interprovincial boundary, under the 1969 Master Agreement on Apportionment, in the period 1912 to 1979 if the present level of use had been in effect.

An array of one-half the natural flow at the interprovincial boundary plus the array of the total water uses at the present level of consumption (Table H-5) were then subtracted from the array of natural flows for the Battle River at the Alberta-Saskatchewan boundary (Table G-1). The results are presented in Appendix I, Table I-1. It should be emphasized that for periods when the consumptive use exceeded the natural flow, the deficit was assumed to be one-half of the natural flow. Within Table I-1, negative values indicate periods when water use in Alberta would have exceeded Alberta's 50% share of the natural flow at the interprovincial boundary. Positive values indicate periods when Saskatchewan would have received more than its 50% share under the apportionment agreement.

CONCLUSIONS

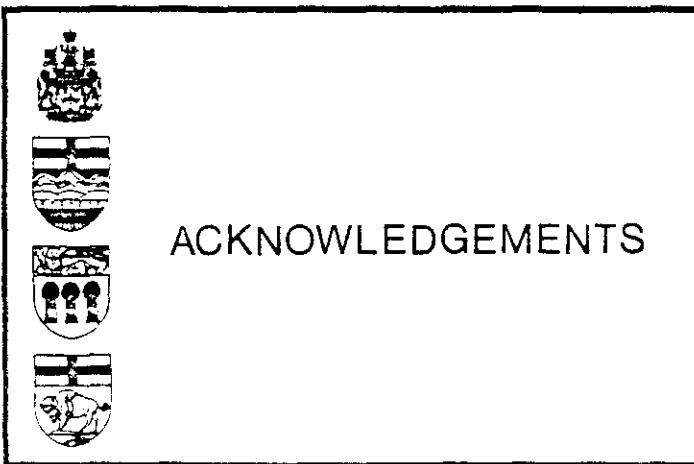

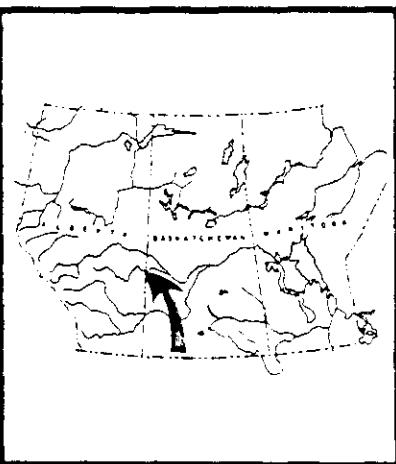

The 13,900 acre-feet of water presently (1979) used in the Battle River basin to the Alberta-Saskatchewan boundary in an average year represents 6.1% of the average annual natural flow of the Battle River at the Alberta-Saskatchewan boundary. At the present level of use there would not have been any years, of the 68 years studied, in which less than 50% of natural flow would have been passed to Saskatchewan. It is of interest to note that the average annual quantity delivered to Saskatchewan in excess of 50% of natural flow during that sixty-eight year period was 101,000 acre-feet. The minimum surplus passed during any one year would have been 3,900 acre-feet in 1941.

Monthly records for Battle River near Unwin have provided an adequate representation of flow at the Alberta-Saskatchewan boundary for historic purposes. This station was relocated in 1980 (Battle River near the Alberta-Saskatchewan Boundary - 05FE004). The new location of this

station will provide a technically more accurate point flow estimate for apportionment purposes but will not change or modify the results of this natural flow study.

If consumptive uses for the Alberta portion of the Battle River are required to be calculated on a continuing basis, five existing hydrometric stations should be operated continuously. They are:

1. Battle River near the Alberta-Saskatchewan Boundary
05FE004
2. Battle River near Ponoka 05FA001
3. Pipestone Creek near Wetaskiwin 05FA012
4. Coal Lake Reservoir near Wetaskiwin 05FA016
5. Alberta Power Reservoir (Recorder operated by Alberta Power).

ACKNOWLEDGEMENTS

The Battle River Natural Flow Study and subsequent report were the responsibility of Mr. S. Figliuzzi, P. Eng., of the Hydrology Branch of the Alberta Department of Environment. The work was carried out under the direction of J.R. Card the present Branch Head.

The helpful advice on various aspects of the study provided by R.B. Godwin, the Executive Director of the PPWB, is gratefully acknowledged.

A special note of thanks must be given to Mohammed Ashraf for his assistance on this study, and to Sharon Ross for her patience in typing numerous report drafts.

TABLE A-2
AUTHORIZED WATER USE IN THE BATTLE RIVER BASIN BETWEEN
THE ALBERTA-SASKATCHEWAN BOUNDARY AND THE BATTLE RIVER'S
JUNCTION WITH THE NORTH SASKATCHEWAN RIVER.

* Based on Computerized data prepared by the Water
Rights Branch of Saskatchewan Environment.

Year	Currently Active Projects (ac.ft.)	Cancelled Projects (ac.ft.)	Total Water Use (ac.ft.)
